# Verbreitungsatlas der Tierwelt Österreichs: Noctuidae sensu classico

M. MALICKY, E. HAUSER, P. HUEMER & C. WIESER

#### Vorwort

Mit dem vorliegenden Band wird die Serie "Verbreitungsatlas der Tierwelt Österreichs" fortgesetzt. Die ersten beiden Bände behandelten die Tagfalter (REICHL E.R., 1992) und die Spinner und Schwärmer (REICHL E.R., 1994) mit ihrer Verbreitung im österreichischen Bundesgebiet und den angrenzenden Gebieten sowie Südtirol.

Dieser Band beinhaltet sämtliche bis September 1999 in der Datenbank ZOBODAT über die Noctuidae gespeicherten Daten. Durch die sehr hohe verfügbare Datenmenge ist eine gute Aussage über die Verbreitung der Tiergruppe möglich. In Anlehnung an die beiden ersten Bände werden im vorliegenden Band zunächst die Verbreitungskarten abgebildet, anschließend sind farbige Bildtafeln der besprochenen Tierarten eingebaut, bei Arten mit einer großen Variabilität sind mehrere Abbildungen enthalten. Die Bildtafeln wurden aus Belegmaterial der Sammlung des Tiroler Landesmuseums Ferdinandeum zusammengestellt.

#### **Inhaltsverzeichnis**

Material und Methoden	4
Nicht erfaßte Arten	4
Systematik und Nomenklatur	5
Kommentare zu kritischen Arten	6
Danksagung	9

Bildtafeln	206
Datenquellen	254
Index	263

#### Material und Methoden

Mit diesem Buch werden einige Änderungen in die Reihe der Atlanten eingeführt: Die Daten in den Verbreitungskarten werden im 10x6 Minuten Raster angezeigt, auf die in den ersten beiden Bänden verwendeten 10x6 Minuten Rastergrenzen wurde hier für eine bessere Übersichtlichkeit verzichtet. Alte Funde (vor 1980) und neue Funde (ab 1980) werden durch die Symbole leerer und ausgefüllter Kreis dargestellt. Datenpunkte der Gebiete außerhalb des österreichischen Bundesgebietes wurden entfernt, um gezielt den Kenntnisstand der Noctuiden in Österreich zu verdeutlichen. Die Verbreitungspunkte wurden nicht durch Interpolation verdichtet, um eine exakte Analyse von Beobachtungspunkten zu ermöglichen und Beobachtungslücken aufzuzeigen. Außerdem wurden mehrere besonders schwer zu bestimmende oder leicht zu verwechselnde Arten sowie Arten mit verwirrender Nomenklatur der behandelten Gruppe kurz besprochen.

Sämtliche Karten wurden mit den Auswertungsprogrammen der biogeographischen Datenbank ZOBODAT erstellt. In Übereinstimmung mit den vorgehenden Bänden werden in diesem Buch Rasterkarten im 10x6 Bogenminutenraster verwendet. Diese Raster stellen in mitteleuropäischen Breiten annähernd ein Quadratraster dar, was den Vergleich von Flächen erheblich erleichtert. Von den meisten Arten ist eine hohe Datenzahl in der Datenbank verfügbar. Die Darstellung als Rasterkarten birgt gegenüber einer Punktkarte den wesentlichen Vorteil, dass unübersichtliche Punktwolken vermieden werden, zu einer gewissen Verschleierung führt diese Form der Darstellung allerdings bei Arten mit geringer Datenzahl oder punktuellem Vorkommen in speziellen Lebensräumen.

Die verwendeten Daten stammen aus der Literatur, aus Museal- und Privatsammlungen und aus Sammeltagebüchern. Eine vollständige Auflistung aller in diesem Buch verwendeten Datenquellen befindet sich im Anhang.

Die Datenaufnahmen entsprechen einem unterschiedlichen Bearbeitungsstand. Aus den Bundesländern Tirol und Steiermark liegt weiteres nicht publiziertes Datenmaterial vor, das hier nicht mehr berücksichtigt werden konnte.

Einige Bundesländermeldungen aus HUEMER & TARMANN (1993) konnten auf Grund fehlender Quellenangaben nicht verifiziert werden. Teilweise handelt es sich dabei um EDV-bedingte Fehler, da durch die Druckerei mehrere fehlerhafte Angaben produziert wurden.

#### Nicht erfaßte Arten

Die Noctuidenfauna Österreichs setzt sich im wesentlichen aus autochthonen Arten sowie mehr oder weniger regelmäßig auftretenden Wanderfaltern zusammen. Im vorliegenden Katalog werden nur diese Arten kartographisch erfaßt, einschließlich der ganz sporadisch auftretenden Irrgäste aus dem Mediterraneum, die aber mutmaßlich aktiv einwandern (darunter einige Catocala-Arten, aber auch Taxa wie Ophiusa tirhaca (CRAMER, 1773), Dysgonia algira (LINNAEUS, 1767), Luperina zollikoferi (FREYER, 1836), Mniotype solieri (BOISDUVAL, 1840), Mythimna loreyi (DUPONCHEL, 1827), Clytie illunaris (HÜBNER, 1813) und andere). Einzelfunde aktiv oder passiv durch Menschen verschleppter Arten sowie Taxa, die ohne menschlichen Einfluß nicht überlebensfähig sind, werden nicht in die Arbeit aufgenommen. Es handelt sich dabei insbesonders um folgende Arten:

Clytie syriaca (BUGNION, 1837) (Niederösterreich)

Chazaria incarnata (FREYER, 1838) (Oberösterreich)

Dasypolia ferdinandi RÜHL, 1892 (Salzburg)

Chrysodeixis acuta (Steiermark)

zweifelhafte Meldung:

Agrotis puta (HÜBNER, 1803) (Niederösterreich)

Mehrere von Karsholt & Razowski (1996) für Österreich gemeldete Arten dürften auf fehlerhaften Fundortzuweisungen beruhen. So wurde z.B. Shargacucullia gozmanyi G. & L. Ronkay, 1994 laut Originalbeschreibung/Typenmaterial nicht in Österreich gefunden, wird allerdings unter der Verbreitung bzw. in der Verbreitungskarte für Teile Südösterreichs inkludiert. Arten wie Xestia viridescens (Turati, 1918) und Euxoa cos (Hübner, 1824) sind im benachbarten Südtirol präsent und mutmaßlich daher versehentlich der österreichischen Fauna zugeordnet worden. Überdies konnten keine Funddaten der Arten Sesamia nonagrioides (Lefebvre, 1827), Proxenus hospes (Freyer, 1831), Ipimorpha contusa (Freyer, 1849) und Diachgyris renigera (Hübner, 1808) für das Bundesgebiet registriert werden.

#### Systematik und Nomenklatur

Die gesamte Systematik und Nomenklatur des Verbreitungsatlas folgt in enger Anlehnung der modernen Fassung der Europäischen Schmetterlinge (KARSHOLT & RAZOWSKI, 1996), sowohl auf Art-, Gattungs- und Familienniveau. Lediglich für wenige Taxa wurden auch neuere Forschungsergebnisse berücksichtigt (HACKER, 1998a und 1998b).

Die Noctuidensystematik der Tiergeographischen Datenbank Österreichs orientierte sich in der ursprünglichen Konzeption insbesonders an FORSTER & WOHLFAHRT (1971). Die historisch vielfach typologisch orientierten Arbeiten (KITCHING, 1984) wurden aber in den letzten Jahren von grundlegenden phylogenetischen Analysen abgelöst. Im Rahmen dieser primär auf morphologischen Merkmalen basierenden Konzepte (KITCHING & RAWLINS, 1998), die inzwischen auch durch molekularbiologische Methoden weitestgehend bestätigt werden (MITCHELL et al., 1997), wurden die Pantheidae als eigene Familie und Schwestergruppe der Lymantriidae definiert. Die Stellung der Nolidae bleibt umstritten. Bei REICHL (1994) wird die Gruppe unter den "Bombyces sensu classico" als Familie behandelt, im Katalog der Schmetterlinge Österreichs (HUEMER & TARMANN, 1993) als Unterfamilie der Noctuidae. Nach KITCHING & RAWLINS (1998), die den Nolidae Familienstatus zuerkennen, gelten die ehemals den Noctuidae zugeordneten Chloephorinae und Eariadrinae nunmehr als Unterfamilien der Nolidae. Weitere systematische Änderungen sind zukünftig vor allem bei den sogenannten "quadrifinen" Noctuidae zu erwarten. Um auch die Verbreitungsbilder der rezent nicht mehr den "Noctuidae sensu classico" zugeordneten Gruppen verfügbar zu machen, werden die Pantheidae und Nolidae (Chloephorinae, Eariadrinae) in diesem Atlas mitbearbeitet.

#### Kommentare zu kritischen Arten

#### Acronicta tridens s.l.

= Artenkomplex: Acronicta tridens ([DENIS & SCHIFFERMÜLLER], 1775) - Acronicta cuspis (HÜBNER, 1813) - Acronicta psi (LINNAEUS, 1758)

Bemerkungen: Diese drei Arten sind äußerlich in der Flügelzeichnung ähnlich und wurden bei fehlender Detailkenntnis der Arten, insbesonders von Acronicta tridens, oftmals verwechselt. Bei der Kontrolle von Sammlungsexemplaren tauchen immer wieder Falschmeldungen aus der Literatur auf. A. tridens bevorzugt als mesothermophile Art trockenere und wärmere Lebensräume im Gegensatz zur hygrophilen A. cuspis.

Determination: Im Farbton und in der Beschuppung aller drei Arten sind deutliche Unterschiede zu finden (KOCH, 1984). Für eine sichere Determination vor allem von A. psi und A. tridens ist jedoch eine Untersuchung der Genitalien empfehlenswert. Im männlichen Geschlecht genügt normalerweise auch ein Entfernen der Beschuppung des letzten Abominalsegmentes um die wichtigen Merkmale sichtbar zu machen.

#### Plusia festucae s.l.

= Artenkomplex: Plusia festucae (LINNAEUS, 1758) - Plusia putnami (GROTE, 1873)

Bemerkungen: *Plusia putnami* wurde frühestens in den 60er-Jahren als in Österreich vorkommend erkannt (Beschreibung der *P. putnami* ssp. *gracilis* im Jahr 1966 durch LEMPKE), ältere nicht überprüfbare Daten von "festucae" sind damit nicht mehr in engerem Sinn zuzuordnen.

Determination: Die Bestimmung anhand des Habitus und des metallischen Fleckes im Vorderflügelapex ist nicht in allen Fällen zutreffend, die Genitalpräparation sollte durchgeführt werden.

#### Diachrysia chrysitis s.l.

= Artenkomplex: Diachrysia chrysitis (LINNAEUS, 1758) - Diachrysia tutti (KOSTROWICKI, 1961)

Bemerkungen: Das Artrecht von *Diachrysia tutti* bleibt unklar, möglicherweise ist es ein infraspezifisches Taxon (REZBANYAI-RESER 1985). Unterschiede ergeben sich vor allem in der Zusammensetzung des Pheromons, die Ansprechbarkeit der Taxa (s. str.) allein nach morphologischen Merkmalen ist nur teilweise möglich. Weil außerdem die Diskussion um das Artrecht erst in den letzten 15 Jahren verstärkt geführt wurde, lassen sich besonders ältere, unbelegte Daten nicht einem der beiden Taxa zuordnen.

Determination: Morphologisch teilweise durch die Ausprägung der Vorderflügelbinde und der Valvenform möglich (PRIESNER 1985).

#### Autographa pulchrina s.l.

= Artenkomplex: Autographa pulchrina (HAWORTH, 1809) - Autographa buraetica (STAUDINGER, 1892)

Bemerkungen: A. pulchrina galt noch bis vor kurzem als eine äußerlich kaum zu verwechselnde Art. KERPPOLA & MIKKOLA (1987) konnten jedoch erstmals für Europa die Schwesterart A. buraetica in Finnland nachweisen, inzwischen ist sie auch unter mitteleuropäischen A. pulchrina-Imagines erkannt worden.

Die Verbreitung von A. buraetica in Österreich ist noch unzureichend bekannt. Während die Art in Skandinavien sowie im nördlichen Mitteleuropa auf moorige Gebiete beschränkt ist,

erscheint die Situation südlich des Alpenhauptkammes indifferent. Dementsprechend ist auch das bisher vorliegende Datenmaterial von A. pulchrina kritisch zu hinterfragen.

Determination: Die habituelle Bestimmung von A. buraetica ist zumeist auf Grund der kontrastreicheren dunklen Färbung sowie der stark gescheckten Vorderflügelfransen möglich. Weitere genitalmorphologische Unterschiede finden sich in der Form der männlichen Vesica sowie dem Ductus und Corpus bursae (vgl. SKOU, 1991).

#### Gattung Abrostola OCHSENHEIMER, 1816

Abrostola triplasia (LINNAEUS, 1758) [= A. trigemina (WERNEBURG, 1864)] - Abrostola asclepiadis (DENIS & SCHIFFERMÜLLER, 1775) - Abrostola tripartita (HUFNAGEL, 1766) [= A. triplasia auct., nec (LINNAEUS, 1758)]

Bemerkungen: Die Verwirrung um den Namen "Abrostola triplasia" hatte seine Ursache in der Sammlung von Linnaeus, die tatsächlich 2 Arten enthält. Durch die kürzlich erfolgte Lectotypenfestlegung (MIKKOLA & HONEY, 1993) wurde dieses Problem gelöst (siehe auch EBERT (1997)). Es ist damit zu rechnen, daß bei manchen Funddaten Verwechslungen vorgekommen sind.

Determination: Meist nach dem Habitus möglich (EBERT 1997). In den gängigen Bestimmungswerken entspricht die Nomenklatur bei KOCH (1984) der oben angeführten (triplasia - asclepiadis - tripartita), bei FORSTER & WOHLFAHRT (1971) ist die oben in eckigen Klammern angegebene Namensgebung in Gebrauch (trigemina – asclepiadis – triplasia).

#### Xanthia sulphurago (DENIS & SCHIFFERMÜLLER, 1775)

(=Xanthia fulvago auct., nec CLERCK, 1759)

#### Xanthia icteritia (HUFNAGEL, 1766)

(=Xanthia fulvago sensu LINNAEUS, 1761)

Bemerkungen: Die beiden Taxa sind grundsätzlich unverwechselbar. Allerdings wurden die Namen vielfach vertauscht und so können einige ältere Daten nicht mehr mit Sicherheit zugeordnet werden. Der Artname X. fulvago wurde zuerst 1759 von CLERCK eingeführt, 1761 auch von LINNAEUS verwendet, der aber nur CLERCK's Namen zitierte und dessen Art fehldeutete (MIKKOLA, 1985). Die CLERCK'sche X. fulvago wurde von späteren Autoren (u.a. HUEMER & TARMANN, 1993) anstelle des heute gültigen Namens Xanthia sulphurago verwendet. Erst neuere Analysen an der Originalfarbtafel CLERCK's ergaben die Artidentität von X. fulvago mit Agrochola helvola (MIKKOLA, 1985). Die Situation wird insofern noch verkompliziert, als der Name X. fulvago im Sinne von Linnaeus von einigen Autoren anstelle des heute gültigen Artnamens Xanthia icteritia verwendet wurde. Die Zuordnung von Literaturdaten läßt sich mit Sicherheit nur mehr von Fall zu Fall über Belegmaterial, biologische Angaben, verwendete Referenzwerke oder gleichzeitigem Auftreten beider Taxa lösen.

#### Mesapamea secalis s.l.

= Artenkomplex: Mesapamea secalis (LINNAEUS, 1758) - Mesapamea didyma (ESPER, 1788) [= Mesapamea secalella REMM, 1983] - Mesapamea remmi REZBANYAI-RESER, 1985 - Mesapamea insolita REZBANYAI-RESER, 1996

Bemerkungen: Die Neubeschreibung von *M. secalella* REMM, 1983, hat zur Erkenntnis geführt, daß *M. secalis* einen Artenkomplex bildet. *M. secalella* wurde später mit dem älteren Namen *M. didyma* synonymisiert und schließlich eine weitere Art mit Vorkommen auch in Österreich, viz. *M. remmi*, beschrieben (REZBANYAI-RESER, 1985). Während aber letztere Art

nur extrem selten nachgewiesen wurde, sind *M. secalis* und *M. didyma* im gesamten Bundesgebiet in unterschiedlicher Abundanz vertreten. Eine Auftrennung der 3 Taxa ist aber erst zu einem kleinen Teil erfolgt. Überdies wurde von REZBANYAI-RESER (1996) noch eine *Mesapamea insolita* aus der Südschweiz beschrieben, aus Österreich liegen bisher keine Funde vor. Auf die Möglichkeit des Vorkommens sollte bei der Determination bedacht genommen werden.

Determination: Gesicherte Bestimmungen sind ausschließlich durch Genitalpräparation möglich (vgl. REZBANYAI-RESER, 1985 und weitere Arbeiten des Autors). Habituell sehr ähnlich ist *Apamea unanimis* (HÜBNER, 1813).

#### Hadena bicruris s.l.

= Artenkomplex: Hadena bicruris (HUFNAGEL, 1766) - Hadena capsincola ([DENIS & SCHIFFERMÜLLER], 1775)

Bemerkungen: *H. bicruris* und *H. capsincola* wurden bis vor kurzem vermengt und von HUEMER & TARMANN (1993) noch als konspezifisch behandelt. Rezente Untersuchungen durch HACKER (1996) ergaben aber, daß es sich um 2 valide Arten handelt, wobei sich die Verbreitungsgrenzen in Österreich überschneiden dürften. *H. bicruris* ist eher im Westen verbreitet, *H. capsincola* im Osten. Sympatrisches Auftreten in Österreich erscheint möglich.

Determination: Mit Sicherheit nur durch Genitalpräparation, vor allem der Weibchen zu unterscheiden (vgl. HACKER, 1996).

#### Diarsia rubi s.l.

= Artenkomplex: Diarsia rubi (VIEWEG, 1790) - Diarsia florida (SCHMIDT, 1859)

Bemerkungen: *D. rubi* und *D. florida* sind zwei sehr schwer zu differenzierende Taxa, deren Artstatus daher immer wieder bestritten wird. Die Falter letzterer Art sind durchschnittlich etwas größer als *D. rubi*. Einige genitalmorphologische Unterschiede, vor allem im Aedoeagus und dem Ductus bursae werden von verschiedenen Autoren erwähnt und abgebildet (FIBIGER, 1993). Wichtig ist außerdem die unterschiedliche Bionomie. *D. florida* kommt ausschließlich in moorigen Biotopen vor und weist in Mitteleuropa nur eine Generation auf, während *D. rubi* bivoltin auftritt und eine weitere Palette von Lebensräumen besiedelt.

Die Verbreitung von *D. florida* in Österreich ist noch unzureichend abgesichert. Ein eindeutiger Schwerpunkt dürfte nach heutigen Kenntnissen im Süden des Bundesgebietes (Kärnten) liegen.

Determination: Gesicherte Bestimmungen sind bei Kenntissen der Bionomie sowie mit Hilfe von Genitalpräparation möglich (FIBIGER, 1990).

#### Noctua janthina s.l.

= Artenkomplex: Noctua janthina (DENIS & SCHIFFERMÜLLER, 1775) - Noctua janthe (BORKHAUSEN, 1792)

Bemerkungen: *Noctua janthe* wurde erst in den letzten Jahren als eigenständige Art von *N. janthina* abgetrennt (MENTZER et al. 1991; FIBIGER 1993). Nach Auffassung von REZBANYAI-RESER (in Vorbereitung) handelt es sich bei *N. janthina* und *N. janthe* allerdings um keine getrennte Arten. Das österreichische Datenmaterial ist meist nicht einem bestimmten engeren Taxon zugeordnet.

Determination: Die beiden Taxa sind nach habituellen Merkmalen zu trennen (FIBIGER 1993).

#### Euxoa tritici s.l.

= Artenkomplex: Euxoa tritici (LINNAEUS, 1761) (=Euxoa crypta (DADD, 1927) - Euxoa nigrofusca (ESPER, 1788) (=Euxoa tritici sensu auct.) - Euxoa eruta (HÜBNER, 1827)

Bemerkungen: Der Artenkomplex um Euxoa tritici zählt zu den konfusionsvollsten in der europäischen Noctuidenfauna. Besonders problematisch erscheint auch die "Form" E. eruta (HÜBNER, 1827), die von manchen Autoren als gute Art angesehen wird. Die Ursachen für die Probleme liegen einerseits in der großen Variabilität der Flügelzeichnung und -färbung, andererseits in den winzigen genitalmorphologischen Unterschieden. Neuerdings wurde in FIBIGER (1997) E. eruta als gute Art anerkannt und damit eine um wenige Jahre ältere Auffassung, wonach es sich lediglich um eine Form handle, revidiert (FIBIGER, 1990). Das Problem wird überdies noch durch die neulich erfolgte Auswahl eines mit E. crypta artidenten Lectotypus von E. tritici verschärft (MIKKOLA & HONEY, 1993). Die bisher als E. tritici angesprochene Art hat daher den nächsten validen Namen, viz. E. nigrofusca (ESPER, 1788) erhalten (EMBACHER, 1999). Eine weitere Bearbeitung mittels Zuchtversuchen aber auch molekuarbiologischen Methoden ist für ein besseres Verständnis des Artenkomplexes dringend nötig. Dementsprechend mit Vorbehalt sind die aus dem Bundesgebiet gemeldeten Daten zu sehen. Eine Auftrennung des österreichischen Materials ist selbst im Sinne von FIBIGER (1990) noch weitestgehend ausständig. Lediglich EMBACHER (1999) meldet alle 3 Taxa, E. tritici, E. nigrofusca und E. eruta aus dem Bundesland Salzburg.

Determination: Die Falter von *E. tritici*-Falter (=*E. crypta*) sind durchschnittlich etwas kleiner und breitflügliger als *E. nigrofusca* (=*E. tritici* sensu auct.) (28-32 mm Flügelspannweite). Gesicherte Bestimmungen sind ausschließlich mittels Genitalpräparation möglich, wobei die wesentlichen, allerdings sehr schwachen Differenzen in der Form der Vesica des Männchens sowie des weiblichen Corpus bursae zu finden sind (vgl. FIBIGER (1990, 1997)).

#### Bena bicolorana (FUESSLY, 1775)

(=Bena prasinana auct., nec (LINNAEUS, 1758))

# Pseudoips prasinana (LINNAEUS, 1758)

(=Pseudoips fagana (FABRICIUS, 1781))

Bemerkungen: Die beiden Taxa sind grundsätzlich unverwechselbar. Allerdings wurden die Namen vielfach vertauscht und so können einige ältere Daten nicht mehr mit Sicherheit zugeordnet werden, dies betrifft insbesonders den Namen *prasinana*. Auch bei HUEMER & TARMANN (1993) liegen noch Verwechslungen vor. Die dort als *B. prasinana* bezeichnete Art ist nach Typenuntersuchungen der Sammlung LINNAEUS'S (MIKKOLA & HONEY, 1993) eine Fehlbestimmung und *B. bicolorana* zu benennen. Die echte *P. prasinana* ist hingegen mit *P. fagana* artident und ersetzt letzteren Namen.

Determination: Beide Arten sind schon äußerlich gut zu unterscheiden. B. bicolorana ist eine größere Art mit zwei scharfen weißen Querstrichen im Vorderflügel und schneeweißen Hinterflügeln. Die kleinere B. prasinana weist eine unscharf abgegrenzte Bindenzeichnung der Vorderflügel auf, sowie gelbliche Hinterflügel im Männchen.

#### **Danksagung**

Dieses Werk konnte nur durch die Zusammenarbeit von vielen begeisterten Schmetterlingssammlern, Amateuren wie "Profizoologen" entstehen. All jenen, die Daten an die ZOBODAT liefern, sei an dieser Stelle herzlichst gedankt. Für die Mithilfe bei der Korrektur der einzelnen Verbreitungskarten möchten wir folgenden Personen besonderen Dank aussprechen: Dr. Eyjolf und Mag. Ulrich Aistleitner, Feldkirch; Gernot Embacher, Salzburg; Ing. Robert Hentscholek, Linz; Franz Lichtenberger, Waihofen/Ybbs; Dr. Gerhard Tarmann, Tiroler Landesmuseum Ferdinandeum, Innsbruck; Josef Wimmer, Steyr.

#### Zu den Autoren:

#### Dr. Erwin Hauser

Geboren am 22.1.1965 in Steyr, Oberösterreich. Studium der Biologie/Zoologie an der Universität Wien. Seit 1992 als Biologe mit den Schwerpunkten Botanik und Lepidopterologie im Rahmen angewandter Naturschutzforschung tätig, seit 1994 bei der Forschungsgemeinschaft Wilhelminenberg am Otto König-Institut Staning bei Steyr angestellt. Lebt in Wolfern bei Steyr.

## Mag. Dr. Peter Huemer

Am 28.10.1959 in Feldkirch geboren. Studium der Biologie und Erdwissenschaften (Lehramt) und anschließend Zoologie an der Universität Innsbruck. Einjähriger Studienaufenthalt am Natural History Museum (London) seit 1987 am Tiroler Landesmuseum Ferdinandeum tätig und dort primär mit unterschiedlichsten ökologischen, faunistischen und taxonomischen Fragestellungen der alpinen Lepidopterologie befasst.

### DI Michael Malicky

Wurde am 4.3.1969 in Klagenfurt geboren und wuchs in Lunz am See in Niederösterreich auf. Nach der Mittelschule studierte er Informatik in Linz und betreut seit 10 Jahren die biogeographische Datenbank ZOBODAT (bis 1999 ZOODAT). Seit 1999 arbeitet er am Biologiezentrum des Oberösterreichischen Landesmuseums als Informatiker.

#### Dr. Christian Wieser

Jahrgang 1959, studierte Biologie an den Universitäten Graz und Wien. Seit 1986 arbeitet er als Sachverständiger für Naturschutz in der Abteilung 20, Unterabteilung Naturschutz beim Amt der Kärntner Landesregierung. 1995 erhielt er den Förderungspreis für Wissenschaft des Landes Kärntens für seine umfassende Bearbeitung der Kärntner Schmetterlingsfauna.
